Positive

Thank you for submitting this task, Tammie. You have demonstrated a solid understanding of Django's ORM and database interactions, particularly through your successful implementation of group creation to manage user roles effectively. It is also excellent to see your implementation of the `get_or_create` method within your logic. This is a highly effective way to fetch an object or cleanly create it if it does not already exist, which helps to avoid data duplication and keeps the codebase incredibly concise and efficient.

Improve

Unfortunately, I need to ask you to resubmit, and I would like to share the following feedback.

Completeness Feedback

1) To start with, similar to the feedback from the previous review, I would encourage you to address the database migration error currently preventing the app from starting up. When attempting to apply migrations, the application throws the following error:

```
django.db.utils.OperationalError: (1050, "Table 'products_review' already exists")
```

I would encourage you to delete the existing migration files within the migrations folders of your apps, ensuring you strictly leave the `__init__.py` files intact. Afterwards, it would be beneficial to drop your current database and recreate it. Once you have a fresh database, you can run `python manage.py makemigrations` followed by `python manage.py migrate` to generate and apply the new migrations. Applying fresh migrations to a new database will ensure your tables are set up correctly and guarantee the project works as intended when cloned to a new machine. Because this error prevents the application from launching properly, I need to ask for a resubmission, unfortunately.

2) I would also encourage you to update the registration form to include an email field. Giving the user the ability to add their email address while registering will ensure that the necessary contact information is saved, which is critical when resetting passwords or sending out invoices.

3) Furthermore, I would encourage you to ensure that you have fully implemented the logic for resetting a user's password to align with the task requirements. The task brief requires that users have a mechanism to recover their accounts. To achieve this, it might be helpful to utilise Django's built-in authentication views, such as `PasswordResetView` and `PasswordResetConfirmView`, along with their corresponding templates and URL routing. As part of setting up this flow, I would also encourage you to include a clear "reset password" button or link directly on your login page. Giving users an immediate and intuitive way to start the recovery process if they have forgotten their credentials is a required deliverable and ensures a seamless, realistic authentication experience.

Style Feedback

1) As a stretch goal, it might be helpful to style each of your webpages using CSS and Bootstrap. Applying a UI framework will greatly enhance the overall user experience by making the interface responsive, modern, and far more professional to navigate.

Overall

Keep working hard, and if you struggle, don't hesitate to book a call with a mentor.

After applying the necessary corrections, noting that this list is partial due to incomplete task sections, I recommend systematically reviewing the PDF to confirm successful implementation of all requirements. Additionally, please run your program post-correction to verify it is error-free.

Also, please note that once this task has been marked as complete, A final score for documentation, efficiency, and code style will be given since this is not the final version of your submission, and changes could affect those areas.
